Relationship of sample, frame, and target population

- U = target population
- F_{pc} = potentially covered; F_c = actually covered

s = sample

Simulation Study

Conclusion Ref

◆□▶ ◆□▶ ▲□▶ ▲□▶ □ のQ@

References

Goals of weighting and estimation

- Project sample s to target population U
- Correct for undercoverage by frame, $U F_{pc}$ (eligible units that cannot be selected)
- Correct for overcoverage by frame (ineligible units that can be selected)
- Undercoverage can be huge problem in nonprobability samples—missing demographic groups (age, race/ethnicity, education levels)

Approaches to inference

- Quasi-randomization
 - Estimate pseudo-inclusion probabilities and use inverses as weights
- Superpopulation modeling
 - Can give weights that apply to any *y* if generally useful set of covariates used
- Combine quasi-randomization and superpopulation model
 - Called "doubly robust" in observational data literature

Simulation Study

Conclusion Re

Quasi-randomization

Quasi-randomization with a reference survey

- Reference survey: a probability survey or a census
- Combine reference sample and nonprob sample
- Fit weighted binary regression to predict probability of being in nonprob sample
 - Code nonprob cases = 1, reference cases = 0
 - Wts for nonprob cases = 1, wts for reference cases = survey weight
 - Estimates: Pr(in nonprob sample) within whatever population the reference sample represents
- Weights are inverses of "pseudo-inclusion" probabilities
- Justification is like repeated sampling in design-based world

Simulation Study

Conclusion Re

・ロト ・ 同 ・ ・ ヨ ・ ・ ヨ ・ うへつ

Superpopulation modeling

Superpopulation modeling

- Reference survey unneeded
- Fit linear regression model of y on covariates
- Use fitted model to predict values for nonsample cases
- Add sample values to nonsample predictions to estimate pop total
 - Estimated total is approximately $\hat{t} = \mathbf{t}_{Ux}^T \hat{\boldsymbol{\beta}}$
 - Predict for every unit in population and add up
 - Only pop totals of *x*'s are needed—not individual *x*'s for nonsample units
- Justification: estimator of total is model-unbiased if model is correct

Simulation Study

Conclusion F

◆□▶ ◆□▶ ▲□▶ ▲□▶ ■ ののの

References

Superpopulation modeling

Standard error estimation

- Quasi-randomization: use design-based variance estimator for with-replacement sampling
 - Ignores fact that pseudo-probabilities are estimates
 - Could replicate to reflect that (jackknife, bootstrap)
- Superpopulation modeling
 - Model-based variance estimators are available
 - Replication also works
- Combination (doubly-robust)
 - Need to replicate to reflect all sources of variability

Superpopulation modeling

Multilevel regression & poststratification

- Variation on superpopulation modeling
- Fit an elaborate model for a poststratum of units
- Estimate a mean or proportion as

$$\hat{ar{y}} = \sum_{\gamma=1}^G \hat{P}_\gamma \hat{\mu}_\gamma$$

 \hat{P}_{γ} = estimated proportion of pop in poststratum γ

 $\hat{\mu}_{\gamma}$ = estimated mean per element in poststratum γ

- PS mean is estimated by random (or mixed) effects model or Bayesian modeling approach
- Begin with cross-classification of many covariates and dynamically decide which crosses to retain

Conclusion Referen

Simulation population

Simulation population

- Pop based on Michigan BRFSS dataset in R PracTools pkg [Valliant, Dever, & Kreuter 2017]
- Demographics—age, race, education, income
- Analysis vars—Self-reported general health, smoked 100 cigarettes in lifetime, good or better health, mean health rating
- N = 50,000 in U; select samples from persons who have Internet access at home (about 65% of pop)
- Similar to [Valliant & Dever, 2011] study but samples here are selected to have substantial undercoverage problem

Outline	The Inferential Problem	Weighting Nonprobability samples	Simulation Study	Conclusion	References
Simulation	population				

Table: Distribution by age of population of persons, subgroup that has Internet access at home, and samples

	Proportions		
Age	Population	Internet	Sample
1 = 18-24	0.06	0.06	0.12
2 = 25-34	0.14	0.16	0.31
3 = 35-44	0.20	0.23	0.19
4 = 45-54	0.22	0.25	0.20
5 = 55-64	0.17	0.18	0.13
6 = 65+	0.22	0.12	0.05
Total	1.00	1.00	1.00

Outline	The Inferential Problem	Weighting Nonprobability samples	Simulation Study	Conclusion	References
Simulation	population				

Table: Proportions of analysis variables in full population and subpop of persons with Internet access at home.

	Smoked 100 cigarettes		Good or better health	
	Population	Internet	Population	Internet
Yes	0.54	0.50	0.84	0.89
No	0.46	0.50	0.16	0.11

Internet subpop smokes less and is more healthy \Rightarrow weighting has a lot to correct for

< □ > < 同 > < 三 > < 三 > < 三 > < ○ < ○ </p>

Simulation Study

Conclusion Ref

Sampling & Estimation

Sampling & Estimation

- Select stratified *srswor* sample from Internet subpop; strata = age
 Fact that sample is *stsrswor* is unknown to analyst
- Sample sizes n = 500 and 1,000
- Reference sample is same size as the nonprob sample
- Repeat 10,000 times
- Estimators
 - Quasi-random
 - Model-based: M1 (linear), M2 (raking)
 - Doubly robust (quasi-random + M1)
- SE estimates: WR design-based; grouped JK (G = 50) with all est steps repeated in each group

Simulation Study

Conclusion Refe

Results

Figure: Quasi-rand has largest |relbias| (with a few_exceptions) and the second second

Outline	The I	nferential	Problem
---------	-------	------------	---------

Simulation Study

Conclusion Refe

Results

Figure: CI coverage is worse for larger n when estimates are biased

◆□▶ ◆□▶ ▲□▶ ▲□▶ □ のQ@

References

Conclusion

- Poor population coverage is difficult to overcome
- Quasi-random was least effective in eliminating bias
- Linear model & raking have similar relbiases
- Jackknife was somewhat better than WR replacement variance estimator
